Task 5- Create CI/CD pipeline to build code and docker image generation.

Overview:

Continuous Integration and continuous delivery/deployment are a set of practices adopted by software development teams to streamline the development process by automating certain processes thereby increasing frequency of releases and quality of final product.

Setup:

For this task GitHub actions was used to create the workflow that takes care of building the docker image.

Repository link: git clone https://github.com/NikhilKumar2444/Kaiburr-Task-5.git

Details:

The workflow runs on the main branch, any commit to the main branch will result in the docker image getting built.

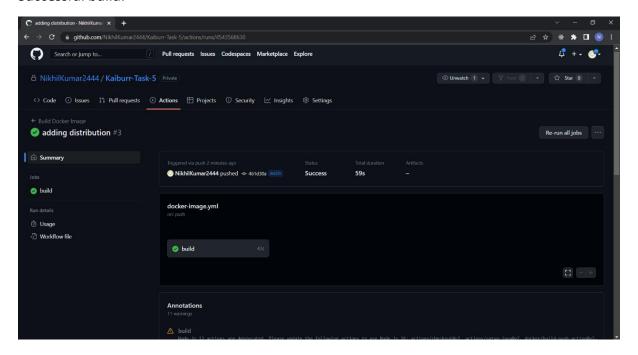

Ubuntu latest is used as a base image as it provides a reliable environment for running build and development work. It ensures same dependencies, libraries and system configurations are used consistently across different machines and environments reducing risk of compatibility issues.

A Dockerfile is created that is used by the pipeline to perform the build of docker image.

docker/build-push-action@v2 command is used to start building the docker image.

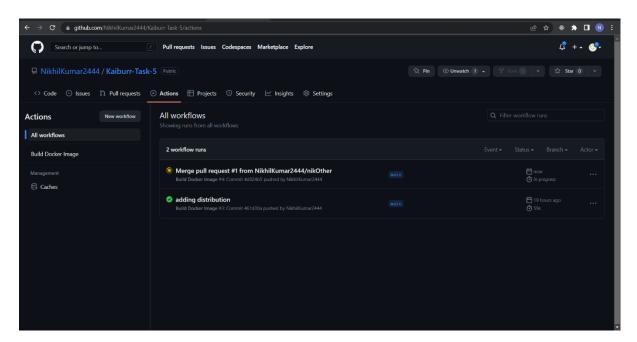

Output screenshots

Successful build.

Separate branches help keep the most stable version of the application in production. Updates, bug fixes, feature addition and much more happens on these separate branches. After successfully pushing to the main branch, the pipeline takes care of the remaining work.

A separate branch called "nikOther" is where we make changes to the application. After these get pushed to the "main" the workflow runs.

Success full Build:
